

Components of a vector

- The **x**- and **y**-components of a vector are its **projections** along the **x**- and **y**-axes
- Calculation of the **x**- and **y**-components involves trigonometry

$$A_x = A \cos \theta$$

$$A_y = A \sin \theta$$

Components of a vector

- If we know the components, we can find the vector.
- Use the **Pythagorean Theorem** for the magnitude:

$$A = \sqrt{A_x^2 + A_y^2}$$

- Use the **\tan^{-1}** function to find the direction:

$$\theta = \tan^{-1} \frac{A_y}{A_x}$$

Displacement & Distance

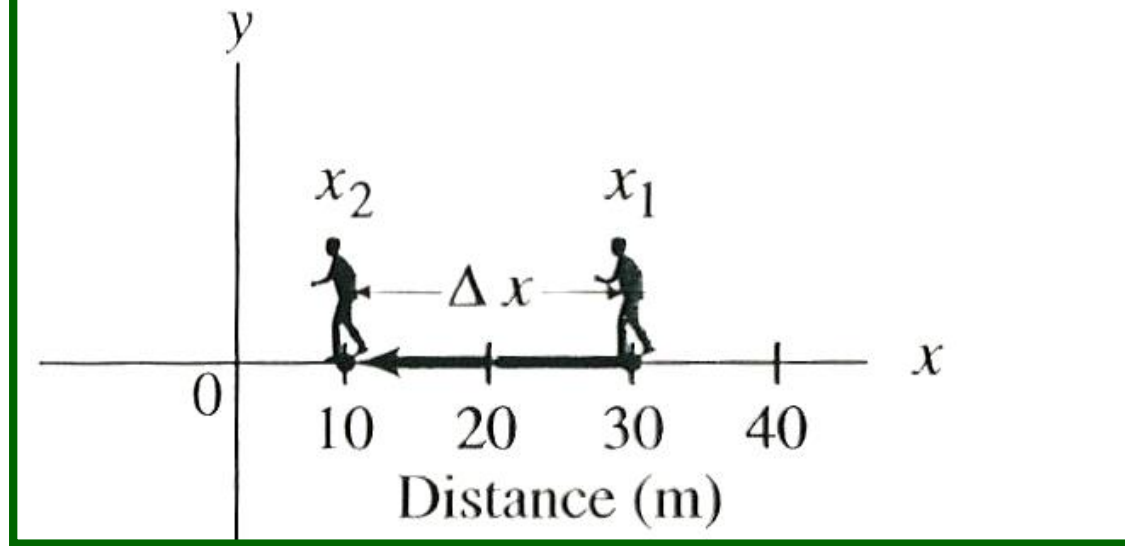

Distance traveled by an object \neq Displacement of the object!

Here,
Distance = 100 m.
Displacement = 40 m East.

- Displacement $\equiv \Delta \mathbf{x} \equiv$ Change in position of an object. $\Delta \mathbf{x}$ is a **vector** (magnitude & direction).
- Distance is a **scalar** (magnitude).

FIGURE 2-6 For the displacement $\Delta x = x_2 - x_1 = 10.0 \text{ m} - 30.0 \text{ m}$, the displacement vector points to the left.

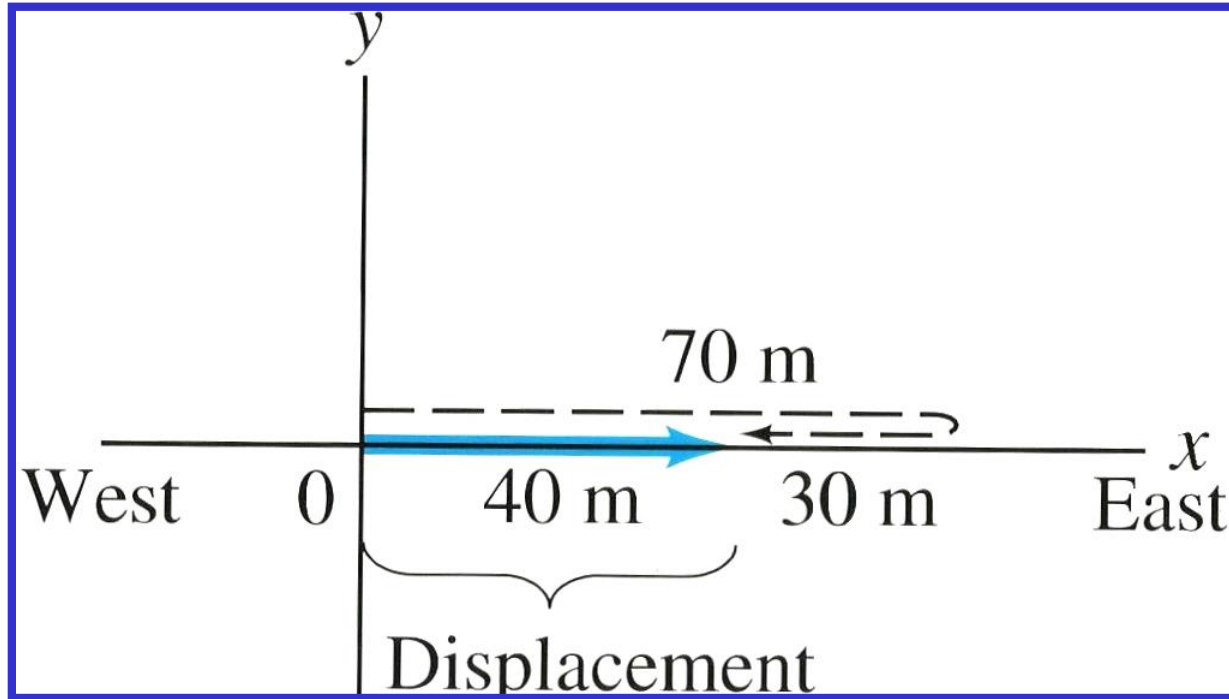

$$\mathbf{x_1 = 30 \text{ m}, x_2 = 10 \text{ m}}$$

$$\mathbf{\text{Displacement} \equiv \Delta \mathbf{x} = \mathbf{x_2} - \mathbf{x_1} = -20 \text{ m}}$$

Average Velocity & Average Speed

Consider the displacement from slide 3.

Suppose that the person walks the whole trip in **70 s**.

$$\underline{\text{Average Speed}} = (100 \text{ m}) / (70 \text{ s}) = 1.4 \text{ m/s}$$

$$\underline{\text{Average Velocity}} = (40 \text{ m}) / (70 \text{ s}) = 0.57 \text{ m/s}$$

Example: Average Acceleration

$$t_1 = 0$$

$$v_1 = 0$$

Acceleration

[$a = 5.0 \text{ m/s}^2$]

A car accelerates along a straight road from rest to **90 km/h** in **5.0 s**. Find the magnitude of its average acceleration.

Note: 90 km/h = 25 m/s

$$a_{\text{ave}} = \frac{\Delta v}{\Delta t} = (25 \text{ m/s} - 0 \text{ m/s})/5\text{s} = 5 \text{ m/s}^2$$

at $t = 1.0 \text{ s}$

$$v = 5.0 \text{ m/s}$$

at $t = 2.0 \text{ s}$

$$v = 10.0 \text{ m/s}$$

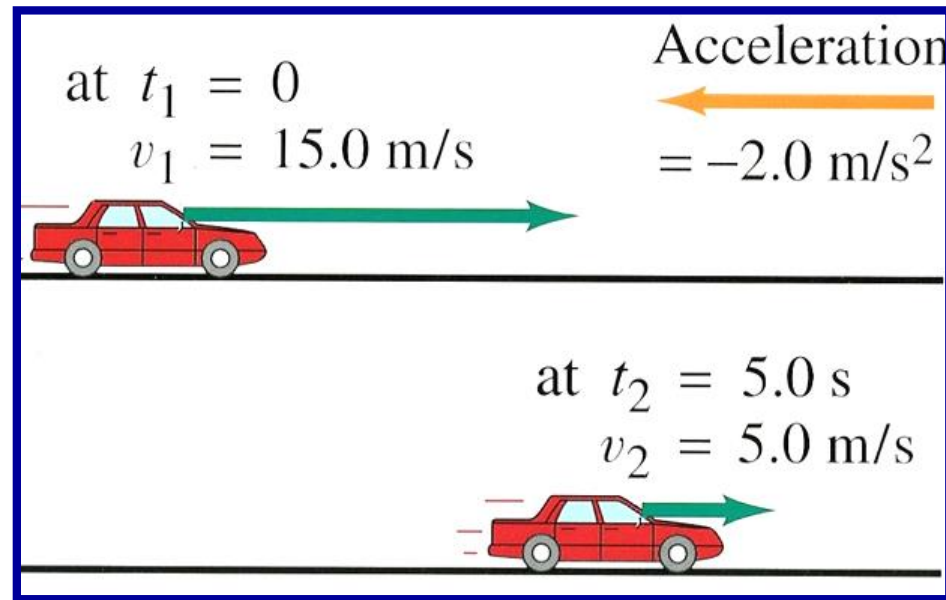

at $t = t_2 = 5.0 \text{ s}$

$$v = v_2 = 25 \text{ m/s}$$

Example: A slowing down car

A car moves to the right on a straight highway (positive **x-axis**). Calculate the car's average acceleration.

$$\mathbf{a} = \frac{\Delta v}{\Delta t} = (v_2 - v_1)/(t_2 - t_1) = (5 \text{ m/s} - 15 \text{ m/s})/(5\text{s} - 0\text{s})$$
$$\mathbf{a} = - 2.0 \text{ m/s}^2$$

Deceleration

The same car is moving to the left instead of to the right. **We still assume positive x is to the right.** The car is “decelerating” & the initial & final velocities are same as before. Calculate the average acceleration now.

$$\begin{aligned} a &= \frac{v_2 - v_1}{\Delta t} = \frac{-5.0 \text{ m/s} - (-15.0 \text{ m/s})}{5.0 \text{ s}} \\ &= \frac{-5.0 \text{ m/s} + 15.0 \text{ m/s}}{5.0 \text{ s}} = +2.0 \text{ m/s}^2 \end{aligned}$$

Deceleration is a misleading term!
